### ASSESSMENT TOOL 2

---

#### Q1. For the grammar $E \rightarrow E + T \mid T$ , remove left recursion.

Given:  $E \rightarrow E + T \mid T$

This is left recursive because  $E \rightarrow E + T$ .

The standard elimination form is:

$$\begin{aligned} E &\rightarrow T E' \\ E' &\rightarrow + T E' \mid \epsilon \end{aligned}$$

**Answer:**  $E \rightarrow T E'$  and  $E' \rightarrow + T E' \mid \epsilon$

#### Q2. Find $\text{FIRST}(E)$ for: $E \rightarrow T E', E' \rightarrow + T E' \mid \epsilon$

Given:  $E \rightarrow T E'$  and  $E' \rightarrow + T E' \mid \epsilon$

Since  $E$  starts with  $T$ :

$\text{FIRST}(E) = \text{FIRST}(T)$

Assuming  $T \rightarrow \text{id}$ :

$\text{FIRST}(T) = \{ \text{id} \}$

**Answer:**  $\text{FIRST}(E) = \{ \text{id} \}$

#### Q3. For the grammar $E \rightarrow T + E \mid T$ , check if it is ambiguous or not.

Grammar:  $E \rightarrow T + E \mid T$

For a string such as  $T + T + T$ , there is only one possible structure:

$T + (T + T)$

The grammar produces only one parse tree for each valid string.

**Answer:** The grammar is unambiguous.

#### Q4. Identify whether the string $aba$ is valid for: $S \rightarrow aSa \mid b$

Grammar:  $S \rightarrow aSa \mid b$

Derivation:

$S \rightarrow aSa \rightarrow aba$

Therefore,  $aba$  is generated by the grammar.

**Answer:** Yes,  $aba$  is valid.

### Q5. Check whether the string $ab$ is generated by: $S \rightarrow aA, A \rightarrow b$

Grammar:  $S \rightarrow aA, A \rightarrow b$

Derivation:

$S \rightarrow aA \rightarrow ab$

**Answer:** Yes,  $ab$  is generated.

### Q6. Construct a parse tree for $a + b * c$ using: $E \rightarrow E + E \mid E * E \mid id$

Grammar:  $E \rightarrow E + E \mid E * E \mid id$

For normal arithmetic precedence,  $*$  has higher precedence than  $+$ , so the expression is grouped as:

$a + (b * c)$

Parse tree structure:

**Answer:** Result:  $a + (b * c)$

### Q7. Apply left factoring for: $S \rightarrow aA \mid aB \mid b$

Given:  $S \rightarrow aA \mid aB \mid b$

The common prefix is 'a'. Factoring it out:

$S \rightarrow aS' \mid b$   
 $S' \rightarrow A \mid B$

**Answer:**  $S \rightarrow aS' \mid b$  and  $S' \rightarrow A \mid B$

### Q8. Find FOLLOW(A) for: $S \rightarrow AB, B \rightarrow b$

Given:  $S \rightarrow AB, B \rightarrow b$

Since A is followed by B:

$\text{FOLLOW}(A) = \text{FIRST}(B)$

Since  $B \rightarrow b$ ,  $\text{FIRST}(B) = \{ b \}$

**Answer:**  $\text{FOLLOW}(A) = \{ b \}$

**Q9. Given the grammar  $S \rightarrow aSb \mid \epsilon$ , check whether the string aaabbb is valid using derivation.**

Grammar:  $S \rightarrow aSb \mid \epsilon$

Derivation:

$S \rightarrow aSb \rightarrow aaSbb \rightarrow aaabbbb \rightarrow aaabbb$

Therefore, aaabbb is generated.

**Answer:** Yes, aaabbb is valid.

**Q10. Convert the following ambiguous grammar into an unambiguous grammar:  $E \rightarrow E + E \mid E * E \mid id$**

Given:  $E \rightarrow E + E \mid E * E \mid id$

This grammar is ambiguous because precedence and associativity are not specified. An unambiguous version enforcing precedence ( $*$  higher than  $+$ ) and left associativity is:

$E \rightarrow E + T \mid T$   
 $T \rightarrow T * F \mid F$   
 $F \rightarrow id$

**Answer:**  $E \rightarrow E + T \mid T, T \rightarrow T * F \mid F, F \rightarrow id$

**Q11. Identify whether the grammar  $S \rightarrow Sa \mid b$  is suitable for top-down parsing.**

Given:  $S \rightarrow Sa \mid b$

The grammar has left recursion ( $S \rightarrow Sa$ ). Top-down parsers such as recursive descent parsers cannot directly handle left-recursive grammars.

Removing left recursion gives:

$S \rightarrow bS'$   
 $S' \rightarrow aS' \mid \epsilon$

**Answer:** The given grammar is not directly suitable for top-down parsing because it contains left recursion.

## Q12. Write a recursive descent parser for the grammar: $S \rightarrow aS \mid b$

C program implementing the recursive descent parser:

```
#include <stdio.h>
#include <string.h>

char input[100];
int pos = 0;

void S()
{
    if (input[pos] == 'a')
    {
        pos++;
        S();
    }
    else if (input[pos] == 'b')
    {
        pos++;
    }
    else
    {
        printf("Error");
    }
}

int main()
{
    printf("Enter string: ");
    scanf("%s", input);
    S();
    if (input[pos] == '\0')
        printf("Valid string");
    else
        printf("Invalid string");
    return 0;
}
```

### Q13. Construct the operator precedence table for: $E \rightarrow E + E \mid E * E \mid id$

Grammar:  $E \rightarrow E + E \mid E * E \mid id$ . Operators: +, \*, id, \$. Since \* has higher precedence than +, the operator precedence table is as follows:

|    | + | * | id | \$ |
|----|---|---|----|----|
| +  | > | < | <  | >  |
| *  | > | > | <  | >  |
| id | > | > | -  | >  |
| \$ | < | < | <  | =  |

### Q14. What is panic mode error recovery?

Panic mode error recovery is a simple error recovery technique used by parsers. When the parser finds an error, it:

1. Discards input symbols.
2. Continues discarding until it finds a synchronizing symbol.
3. Common synchronizing symbols are ; , } , or \$.
4. Parsing then continues from that point.

Example: `int a = ; int b = 10;`

The parser detects an error at '=' because an expression is missing. It skips input until a suitable symbol such as ';' is found and then continues parsing.

**Answer:** Panic mode recovery skips erroneous input until a synchronizing token is found, allowing parsing to continue.

### Q15. Why is error recovery important in parsing?

Error recovery is important because it allows the compiler to continue parsing after finding an error instead of stopping immediately.

Main advantages:

1. Detects multiple errors in one compilation.
  2. Prevents the compiler from stopping at the first error.
  3. Gives better error messages.
  4. Saves time during debugging.
  5. Helps the compiler continue processing the remaining program
- Answer:** Error recovery improves the compiler's ability to detect and report multiple errors efficiently while continuing the compilation process.
